

A cap on the impact parameter imposes a smallest kick magnitude q_* ; the peak in $d\sigma/dq$ is the last surviving horn

A. One flyby: $q_z = q_\perp \cos \phi$

B. Many flybys, no cap: every q is somebody's horn

C. Cap $b \leq b_{\text{cap}}$: kicks below q_* are gone

D. The peak sits at q_* for every b_{cap}
