

The α^2/m degeneracy of the long-range ($1/r^2$) interaction: identical signal from ever-larger impact parameters

Bare-halo SHM without atmosphere (attenuation would break the degeneracy at high α and is irrelevant to the geometric point); mode-1 measured efficiency; μ anchored at the $\langle N \rangle = 3$ zero-event benchmark. Panel B is the same μ pipeline run with the capped massless cross section, differentiated in $\log_{10} b$.
